AB The present invention relates to the use of an alkaline or alkaline earth metal chondroitin sulfate, which comes from an enzymic hydrolysis of animal cartilage, for the preparation of a medicament for the treatment or prevention of psoriasis with skin affection in a mammal. Preferably the sodium chondroitin sulfate has an average mol. weight between 10,000 and 20,000 daltons, and is administered orally. A tablet contained sodium chondroitin sulfate (13,000-18,000 daltons) Avicel PH 200 292.0, Aerosil 200 1.0, and magnesium stearate powder 7.0 mg. Efficacy of the tablets in the treatment of psoriatic patients is shown.

AB This invention provides gene expression profile between a rash site and a no-rash site in a patient with atopic dermatitis or a patient with psoriasis. The invention also provides gene expression profile between a no-rash site in such a disease and a normal subject. Animal models, particularly mouse for those diseases are also claimed. The gene expression profile provided in this invention can be used for diagnosis, therapy, and drug screening for atopic dermatitis and psoriasis.

AB Employing the cetyltrimethylammoniumbromide precipitation procedure for total glycosaminoglycan (GAG, acid mucopolysaccharide) excretion, the urine of a 58 year old male with psoriatic erythroderma (in whom the clin. picture was suggestive of lichen myxoedematosus, although histol. examination supported a diagnosis of psoriasis) had an almost 4-fold increase in total GAG excretion, most of which consisted of low-sulfated heparan sulfate (LHS), during the acute erythrodermic stage of the disease. The absence of chondroitin sulfate from the urinary GAG at this stage was striking. In the subacute stage of the erythroderma, both total excretion of GAG and the relative proportion of LHS excreted decreased. After the disappearance of erythroderma, GAG excretion was normalized. Thus, the excretion of LHS in the case reported correlated with the intensity and the extent of the erythrodermic skin reaction, which was apparently associated with a profound change in HS metabolism Whether this hitherto unknown metabolic derangement occurred generally in psoriatic erythroderma, or was confined to some subtype of the disease (e.g., with coexisting benign gammopathy) had still to be investigated.

DOCUMENT TYPE: Journal
LANGUAGE: Russian
AB Alterations in mucopolysaccharides (I) of the skin were studied histochem. in 12 patients with psoriasis. Staining with Toluidine Blue gave γ-metachromasia, not only in the epidermis, but also in the cutis proper, which was especially pronounced in the stationary stage of psoriasis. The I made apparent most rapidly was chondroitin sulfate B, as treatment with lidase did not result in loss of metachromasia. In the dermis there was also a substance giving a pos. Schiff-periodic acid reaction which did not disappear following treatment with amylase. Together with alterations of I in the epidermis, significant changes in acid and neutral I occur in the dermis. It is suggested that formation of free acid I occurs as a result of proteolytic processes which break down complex protein-carbohydrate components in the ground substance of the dermis proper. The presence of similar histochem. changes in clin. unaffected skin of patients with psoriasis (2 biopsies) is, to a certain extent, evidence favoring a systemic character of the disease.

AB Psoriasis scales were washed with Et2O, dried, and homogenized in a Waring Blendor with a borate buffer at pH 9.4 for 15 min. (10 g. scales/100 ml. buffer). The scales were extracted for 48 hrs. at 6°, filtered, and dialyzed 24 hrs. against the buffer at 6°. Three proteins (I, II, III) were precipitated maximally at 30, 60, and 80% saturation with (NH4)2SO4. I, II, and III were dialyzed against distilled H2O and repptd. at their isoelec. points. I, II, and III were identified in the concentrated filtrate by use of electrophoresis. I was very similar or identical to tonofibrin. II was a globular protein with an isoelec. point of 4.2. It precipitated first as a fine flocculant substance and on concentration by centrifugation it took on a gelatinous appearance. On drying and exposure to air, it turned a brown-black color. It was not precipitated by heat. Analysis gave mercapto groups. Paper electrophoresis and staining with a buffered thionin solution at pH 4.0 gave a protein band which exhibited striking metachromasia which was destroyed by incubation with testicular hyaluronidase or malt diastase. II gave pos. tests for glycoprotein. Some evidence was obtained that the carbohydrate radical of II was chondroitin sulfate. III was shown to be a nucleoprotein having an isoelec. point of 3.4. I, II, and III were absent in callus. Normal epidermis gave I, II, and III; II was present in very small amts. Two cases of nonpsoriatic exfoliative dermatitis gave 2 proteins, II and that present in callus; from these studies it appears that intracellular glycoprotein is present in psoriasis only. It is suggested that the demonstration of I, II, and III on paper strips may be used as a diagnostic and prognostic tool in psoriasis.

AB Chondroitin sulfate (CS) is a linear heteropolysaccharide consisting of repeating disaccharide units of glucuronic acid and galactosamine, which is commonly sulfated at C-4 and/or C-6 of galactosamine. The administration of CS as a supplement or a drug for the treatment of osteoarthrosis, the prevention of subsequent

coronary events, treatment of psoriasis and ophthalmic diseases has been suggested. Much debate on the metabolism of CS and therefore the effectiveness of these treatments, especially after oral administration, has arisen due to the macromolecular nature of CS. Difficulties in analysing CS in blood due to the low endogenous concentrations and the covalent and anionic complexes with proteins have hampered the resolution of these issues. In this review, the information on the pharmacokinetics of CS obtained from studies in experimental animals and in humans is presented. Emphasis has been given to the analytical methods used for the determination of glycosaminoglycans, intact CS and CS-derived disaccharides in blood serum and plasma.

AB We describe the clinical and histopathological results of plaque psoriasis in eleven adult patients with knee osteoarthritis and long-standing, moderate to severe psoriasis resistant to conventional therapy treated with chondroitin sulfate. Patients received 800 mg per day of chondroitin sulfate for 2 months. Skin biopsies were obtained before and after treatment. All patients but one presented a dramatic improvement of the condition of the skin, with a reduction of swelling, redness, flaking, and itching (clearance of psoriasis in one patient), increase in the hydration and softening of the skin, and amelioration of scaling. Histopathologically, there was a statistically significant decrease in epidermal thickness, a decrease in the thickness between the stratum basale and the stratum granulosum, a significant improvement of the degree of psoriasis activity, and a decrease in the number of keratinocytes stained with Ki-67. The confirmation of these serendipitous findings in controlled prospective studies could represent an important advance in the therapeutic armamentarium for patients with psoriasis given the excellent safety profile of chondroitin sulfate.

AB BACKGROUND AND OBJECTIVE: After prescribing chrondroitin sulfate for the symptomatic treatment of osteoarthritis, it has been observed that some patients with concomitant psoriasis experience a marked improvement of skin lesions. We describe the clinical and histopathological results of the erythematous and desquamative plaques of three patients with osteoarthritis and psoriasis treated with chondroitin sulfate. PATIENTS AND METHOD: Three adult patients with bilateral knee osteoarthritis and long-standing psoriasis characterized by extensive erythematous, desquamative, and hyperkeratotic plaques, which were resistant to different treatment modalities, received 800 mg/day of chondroitin sulfate during two months. Skin biopsies were obtained before and after treatment. RESULTS: All three patients presented a marked clinical improvement in both pathologies. In addition to a decrease in the thickness of the epidermis (total epidermal thickness, maximal thickness from the basal layer to the beginning of the corneal layer, and maximal thickness of the corneal layer), a decrease in the number of keratinocytes in the proliferative phase, a decrease in the degree of psoriatic activity, and a substitution of parakeratotic keratinization by orthokeratotic keratinization were observed. CONCLUSIONS: The administration of chrondroitin sulfate resulted in a significant clinical and histological improvement of the psoriatic lesions. The confirmation of these preliminary results in future clinical trials could represent an important advance in the therapeutic armamentarium of patients with psoriasis given the excellent safety profile of this drug.

AB Chondroitin sulfate (CS) belongs to the group of glycosaminoglycans (GAGs), which are linear polysaccharides, located in the extracellular matrix and on the cell surface. To study the structure and distribution of CS in human skin and skin disorders, we have selected antibodies using phage display technique against CS. Four unique human anti-CS single-chain antibodies were selected: IO3D9, IO3H10, IO3H12, and IO4C2. We determined their amino acid sequence and evaluated their CS reactivity using ELISA and immunohistochemistry. Antibodies were reactive with CS, but not with other GAGs except for IO4C2, which was also reactive with heparin. Antibody IO3D9 showed a strong reactivity with highly sulfated CS (CSE). All antibodies displayed a different staining pattern in rat kidney, indicating the recognition of unique CS epitopes. In normal skin, the papillary dermis but not the reticular dermis was strongly stained. Antibody IO3H12 also stained basal keratinocytes. We applied these antibodies to study CS expression and localization in melanoma and psoriasis. A strong immunoreactivity with the extracellular matrix of melanoma metastases could be observed for all four antibodies, while in atypical nevi a less extensive reactivity with only the papillary dermis was observed. In psoriatic lesions, CS could be observed in the papillary dermis and in the reticular dermis, whereas the specific location in the papillary dermis found in normal skin was completely lost. In conclusion, human phage-display-derived anti-CS antibodies have been selected, characterized, and applied to detect CS alterations in skin conditions. Altered CS composition was detected in melanoma and psoriasis.

AB Disclosed are compns. for treating psoriasis. One embodiment of the present invention is a composition for treating psoriasis comprising L-lysine, glucosamine, chondroitin and methylsulfonyl methane. Another embodiment of the present invention is a method for the treatment of psoriasis comprising orally administering a composition comprising L-lysine, glucosamine, chondroitin, and methylsulfonyl methane. Another embodiment of the present invention is a system for the treatment of psoriasis comprising one or more packets of one or more tablets for oral consumption, wherein the tablets comprise L-lysine, glucosamine, chondroitin and methylsulfonyl methane. For example, formulation was prepared containing L-lysine 1500 mg, glucosamine 3000 mg, chondroitin sulfate 1800 mg, and methylsulfonyl methane 1500 mg.

AB A review. Chondroitin sulfate (CS) is a linear heteropolysaccharide consisting of repeating disaccharide units of glucuronic acid and galactosamine, which is commonly sulfated at C-4 and/or C-6 of galactosamine. The administration of CS as a supplement or a drug for the treatment of osteoarthrosis, the prevention of subsequent coronary events, treatment of psoriasis and ophthalmic diseases has been suggested. Much debate on the metabolism of CS and therefore the effectiveness of these treatments, especially after oral administration, has arisen due to the macromol. nature of CS. Difficulties in analyzing CS in blood due to the low endogenous concns. and the covalent and anionic complexes with proteins have hampered the resolution of these issues. In this review, the information on the pharmacokinetics of CS obtained from studies in exptl. animals and in humans is presented. Emphasis has been given to the anal. methods used for the determination of glycosaminoglycans, intact CS and CS-derived disaccharides in blood serum and plasma.

AB The authors report the first example of synthetic chondroitin sulfate (CS) microarrays to rapidly identify glycosaminoglycan-protein interactions and probe the specificity of proteins for distinct sulfation sequences. Using the microarrays, the authors identify a novel interaction between CS and TNF-α, a proinflammatory cytokine involved in rheumatoid arthritis, Crohn's disease, and psoriasis . Moreover, the authors demonstrate that CS-E tetrasaccharides and polysaccharides enriched in the CS-E sulfation motif can inhibit the activity of this therapeutically important cytokine. The authors anticipate that carbohydrate microarrays will accelerate understanding of glycosaminoglycan-protein interactions and the role of sulfation in modulating physiol. and disease states.

AB Highly purified and specific glycosaminoglycan-degrading enzymes, chondroitinase B and chondroitinase AC, are used to treat fibroproliferative diseases. The enzymic removal of chondroitin sulfate B (dermatan sulfate), and to a lesser extent, chondroitin sulfate A or C, from cell surfaces effectively decreases growth factor receptors on the cells and thereby decreases the cell proliferative response to such growth factors. In

addition, removal of chondroitin sulfates reduces secretion of collagen, one of the major extracellular matrix components. Through the combined inhibition of fibroblast proliferation and collagen synthesis, treatment with chondroitinase B or chondroitinase AC decreases the size of fibrous tissue found in psoriasis, scleroderma, keloids, pulmonary fibrosis and surgical adhesions.

AB A highly purified and specific glycosaminoglycan degrading enzyme, chondroitinase AC, and to a lesser extent, chondroitinase B, can be used in the treatment of metastatic cancers and in other disorders characterized by angiogenesis. The enzymic removal of chondroitin sulfates A and C, and to a lesser extent, chondroitin sulfate B, from cell surfaces directly decreases the ability of tumor cells to invade blood vessels and thus prevents the formation of metastatic, or secondary tumors; inhibits tumor cell growth; and decreases angiogenesis by inhibiting both endothelial cell proliferation and capillary formation. Decreasing the formation of new blood vessels into the tumor in turn decreases the potential for tumor growth, and further decreases the ability of tumor cells to invade the bloodstream. These effects are opposite to the pro-metastatic effects of tumor-secreted heparanase.

AB A highly purified and specific glycosaminoglycan degrading enzyme, chondroitinase AC, and to a lesser extent, chondroitinase B, can be used in the treatment of metastatic cancers and in other disorders characterized by angiogenesis. The enzymic removal of chondroitin sulfates A and C, and to a lesser extent, chondroitin sulfate B, from cell surfaces directly decreases the ability of tumor cells to invade blood vessels and thus prevents the formation of metastatic, or secondary tumors; inhibits tumor cell growth; and decreases angiogenesis by inhibiting both endothelial cell proliferation and capillary formation. Decreasing the formation of new blood vessels into the tumor in turn decreases the potential for tumor growth, and further decreases the ability of tumor cells to invade the bloodstream. These effects are opposite to the pro-metastatic effects of tumor-secreted heparanase.

AB A topical composition which contains ≥1 polyanion, in particular a linear polyanion such as a sulfated glycosaminoglycan, and vitamin A and/or a vitamin A precursor is suitable for use against skin diseases such as skin cancer, viral or dermatophyte infections, excessive scar tissue formation, connective tissue induration, ulceration, or irritation of superficial veins. Thus, a skin cream composition contained 400 mg pentosan polysulfate and 3 + 106 IU retinol palmitate in 100 g cream base.

Similar compns. may be administered i.m. or i.v. for treatment of malignant tumors.

AB Glucosamine is a popular nutritional supplement for OA. This supplement has shown moderate efficacy in meta-analysis and large industry-sponsored clinical trials. However, smaller independent studies have not shown significant benefit. It is difficult to compare these clinical trials due to heterogeneity in trial design, differences in glucosamine products, and differences in osteoarthritic populations being studied. The National Center for Complementary and Alternative Medicine and the National Institute of Arthritis and Musculoskeletal and Skin Disease (NIAMS/NCCAM) have funded a multicenter five arm placebo controlled study called The Glucosamine Arthritis Intervention Trial (GAIT). GAIT spans 24 weeks, enrolling 1588 subjects, at 13 centers comparing the efficacy of glucosamine sulfate, chondroitin sulfate, glucosamine with chondroitin, to placebo and compared to celecoxib for knee OA. This study may have final data in March 2005.

AB Glucosamine sulfate and chondroitin sulfate are being used by many patients for the treatment of osteoarthritis. Despite a number of studies supporting efficacy of these agents for palliation of joint pain in patients with osteoarthritis, the American College of Rheumatology Subcommittee on Osteoarthritis believes that it is too early to issue recommendations for use. Currently, the National Institute of Arthritis and Musculoskeletal and Skin Diseases in collaboration with the National Center for Complementary and Alternative

Medicine have begun a pivotal study to thoroughly evaluate these agents.

AB The invention concerns chondroitin sulfate-containing ointments for the effective local treatment of dry and/or aging skin and varicose veins. The compound composed of mucopolysaccharide, which is a component of the skin, together with the hyaluronic acid, which has a similar composition, is emptied from the epidermal cells, whose structure changes as a result, it becomes thinner and is not able to bind enough water. Through the addition of chondroitin sulfate, the hyaluronic acid production increases, the adhesion of the horn scales improves, the epidermis becomes thicker and flexible. Furthermore, the composition is effective in the treatment of aesthetically or medically unpleasant skin conditions caused by varicose veins. The chondroitin sulfate is made into a spreadable aqueous composition, together with cosmetol. and pharmaceutically acceptable carriers and fragrances. Thus a cream was prepared from (g): cetyl stearyl alc. 45; stearin 100; glycerin (85%) 100; sorbitol 35; sodium lauryl sulfate 5; chondroitin sulfate sodium salt 5; water 705; 4-hydroxy benzoic acid Me ester 1; ethanol (96%) 10 mL. The cream was stable for at least one year when stored in a closed container at room temperature

AB Chondroitin sulfate increases around a lesion site after central nervous system injury and is believed to be an impediment to axonal regeneration, because administration of chondroitinase ABC, a chondroitin sulfate-degrading enzyme, promotes axonal regeneration of central neurons. To examine the physiol. role of chondroitin sulfate up-regulation after injury, the nigrostriatal dopaminergic axons were unilaterally transected

in mice, and chondroitinase ABC was then injected into the lesion site. In mice transected only, tyrosine hydroxylase-immunoreactive axons did not extend across the lesion at 1 or 2 wk after the transection. Immunoreactivities of chondroitin sulfate side chains and core protein of NG2 proteoglycan increased in and around the lesion site, and a fibrotic scar containing type IV collagen deposits developed in the lesion center. In contrast, in mice transected and treated with chondroitinase ABC, numerous tyrosine hydroxylase-immunoreactive axons were regenerated across the lesion at 1 and 2 wk after the transection. In these animals, chondroitin sulfate immunoreactivity remarkably decreased, and immunoreactivity of 2B6 antibody, which recognizes the stub of degraded chondroitin sulfate side chains, was enhanced. Furthermore, the formation of a fibrotic scar and a glia limitans that surrounds the former was completely prevented; although, type IV collagen immunoreactivity remained in newly formed blood capillaries around the lesion site. We discuss the question of whether the chondroitin sulfate is acting as a direct inhibitor of axonal regeneration or whether the observed changes are due to a prevention of the fibrotic scar formation and a rearrangement of astrocytic membranes.

AB To characterize decorin and chondroitin sulfate (CS) expression in lichen sclerosus (LS). Thirty-one untreated vulvar LS lesions were biopsed, and hematoxylin-eosin-stained cases were graded according to Hewitt's classification. Immunohistochem. was performed using antibodies directed against human decorin diluted 1:500 and CS diluted 1:200. The control group, made up of cutaneous fragments from vulvoperineal corrective surgeries or nymphoplasties, represented 22 patients. Decorin and CS were present at the LS hyaline zone in different moments of matrix modulation. In all Hewitt stages CS prevailed at the extracellular matrix in cases with a compact aspect of the hyaline zone, while decorin was seen only in areas of less compactness. Normal vulvar tissue revealed only the presence of CS in juxtaepithelial zones. No decorin immunoexpression was found in normal vulvar skin. Decorin and CS deposition in vulvar LS varies in the distinct histol. stages, which probably reflect the importance of these mols. in matricial remodeling in this disorder. Decorin may play an important role in cases of LS.

AB Claimed are cosmetics which comprise sodium chondroitin sulfate (one of mucopolysaccharides) together with at least one member selected from the group consisting of water, butylene glycol, pentanediol, talc, kaolin, mica, sericite, mica titanium, titanium oxide, benzoic acid salts and phenoxyethanol. These cosmetics contain 0.001 to 5% by weight of sodium chondroitin sulfate which is obtained from salmon and has an average mol. weight of 50,000-300,000. Thus, it is possible to provide cosmetics which can improve the moistness and tension of the skin, keep in good skin condition by

preventing/ameliorating sensitive skin, rough skin, wrinkles, freckles, pimples, spots and so on, preventing the skin form aging and impart a moist and favorable texture to the skin.

AB Skin conditioners contain exts. of poultry skin treated with enzymes, e.g. thermoase, nucleisin, actinase, pepsin, papain, etc., which contain collagens, hyaluronic acid, and chondroitin sulfate. Also claimed are cosmetics and food containing the conditioners. Skin tissue of chicken broiler was minced, autoclaved with H2O, crushed after removing fats, treated with actinase at pH 8 and 40° for 5 h, filtered, and then freeze-dried to give a powdery skin conditioner. The conditioner remarkably reduced rough skin and wrinkle in UVA-irradiated mice. Cosmetic creams, bath prepns., etc., containing the skin conditioners were also formulated.

PRIORITY APPLN. INFO.: JP 1985-283058 19851218

AB Cosmetic packs for skin conditioning of the face are prepared in a form of sheet containing chemical modified collagens such as esterified atelocollagens, succinylated atelocollagens, acylated-succinylated atelocollagen, alkali-solubilized collagens, succinylated alkali solubilized collagens, and acylated alkali-solubilized collagens. Hyaluronic acid, chondroitin sulfate, or other mucopolysaccharide may be added. These materials may be laminated with other synthetic polymer films or sheets. As compared to conventional packs, these collagen materials provide moisture to a larger extent and control skin disorders. Thus, 1% solution of succinylated atelocollagen was prepared and used to make 20 μm-thick film by the drum method. The film was soaked with H2O and placed on the skin for 2 h.

AB A cellulose-protein complex is a normal, although minor, constituent of mammalian connective tissue; higher concns. were observed in certain pathol. human skin conditions. Expts. on the degradation of collagen by treatment with alkaline buffers have afforded histochem. evidence for the production of highly anisotropic fibers. Chemical and phys. studies show that these fibers consist of a protein-polysaccharide complex, the polysaccharide fraction of which is indistinguishable from native cellulose, arranged in helical form round a protein template. The question of fibrogenesis is discussed in the light of synthetic studies whereby anisotropic fibers having similar properties to those of native mammalian cellulose fibers can be obtained by the interaction of gelatin, chondroitin sulfate, and Ca ions.

AB Chondroitin sulfate (CS) belongs to the group of glycosaminoglycans (GAGs), which are linear polysaccharides, located in the extracellular matrix and on the cell surface. To study the structure and distribution of CS in human skin and skin disorders, we have selected antibodies using phage display technique against CS. Four unique human anti-CS single-chain antibodies were selected: IO3D9, IO3H10, IO3H12, and IO4C2. We determined their amino acid sequence and evaluated their CS reactivity using ELISA and immunohistochemistry. Antibodies were reactive with CS, but not with other GAGs except for IO4C2, which was also reactive with heparin. Antibody IO3D9 showed a strong reactivity with highly sulfated CS (CSE). All antibodies displayed a different staining pattern in rat kidney, indicating the recognition of unique CS epitopes. In normal skin, the papillary dermis but not the reticular dermis was

strongly stained. Antibody IO3H12 also stained basal keratinocytes. We applied these antibodies to study CS expression and localization in melanoma and psoriasis. A strong immunoreactivity with the extracellular matrix of melanoma metastases could be observed for all four antibodies, while in atypical nevi a less extensive reactivity with only the papillary dermis was observed. In psoriatic lesions, CS could be observed in the papillary dermis and in the reticular dermis, whereas the specific location in the papillary dermis found in normal skin was completely lost. In conclusion, human phage-display-derived anti-CS antibodies have been selected, characterized, and applied to detect CS alterations in skin conditions. Altered CS composition was detected in melanoma and psoriasis.

PRIORITY APPLN. INFO.: HU 2002-3446 20021014

AB The invention concerns chondroitin sulfate-containing ointments for the effective local treatment of dry and/or aging skin and varicose veins. The compound composed of mucopolysaccharide, which is a component of the skin, together with the hyaluronic acid, which has a similar composition, is emptied from the epidermal cells, whose structure changes as a result, it becomes thinner and is not able to bind enough water. Through the addition of chondroitin sulfate, the hyaluronic acid production increases, the adhesion of the horn scales improves, the epidermis becomes thicker and flexible. Furthermore, the composition is effective in the treatment of aesthetically or medically unpleasant skin conditions caused by varicose veins.
The chondroitin sulfate is made into a spreadable aqueous

composition, together with cosmetol. and pharmaceutically acceptable carriers and fragrances. Thus a cream was prepared from (g): cetyl stearyl alc. 45; stearin 100; glycerin (85%) 100; sorbitol 35; sodium lauryl sulfate 5; chondroitin sulfate sodium salt 5; water 705; 4-hydroxy benzoic acid Me ester 1; ethanol (96%) 10 mL. The cream was stable for at least one year when stored in a closed container at room temperature

AB Disclosed is a type VII collagen gene promoter-activating agent, suitable for use in wrinkle-preventing and anti-aging skin composition, wherein the agent is characterized by containing a compound represented by a general formula I (X = H, OH, methoxy; Y = H, OH, methoxy; m = 0-3; n = 0-2), or lutein. A skin composition containing the type VII collagen gene promoter-activating agent and other active component, e.g. a skin-whitening agent, antioxidant, antiinflammatory agent, cell activator, and/or UV-blocking agent, is also disclosed. Thus, the effects of flavone, 5-hydroxyflavone, chrysin, 5,2'-dihydroxyflavone, eupatorin, luteolin, genkwanin, baicalein, lutein, and apigenin on activation of transcription of type VII collagen gene promoter were in vitro examined Also, a cosmetic lotion containing the type VII collagen gene promoter activator 0.1 % with other ingredients was formulated.

AB Dermal delivery for the treatment of skin disorders offers numerous potential advantages over conventional therapies including avoidance of hepatic first pass metabolism, improved patient compliance, lower systemic absorption and reduced side effects. Previous studies by the authors have shown that hyaluronan (HA) is more effective than other gel-forming materials in localizing the delivery of radiolabeled diclofenac within the epidermis of human skin. Such phenomena have also been reported in vivo in both mice and humans and have helped to facilitate the regulatory approval of a topical HA/diclofenac formulation for the treatment of actinic keratosis. However, a mechanism of action to explain the topical delivery properties of HA remains to be elucidated. The aim of this study was to compare the effect of HA with other

glycosaminoglycans and pharmaceutically relevant polysaccharides on the thermodn. activity and percutaneous penetration of diclofenac and ibuprofen. The dermal partitioning of diclofenac and ibuprofen in various concns. of HA, chondroitin sulfate (CS), heparin (HP), sodium CM-cellulose (NaCMC) and pectin were determined The results from these studies were then compared to Franz cell skin deposition studies. The studies demonstrated that HA significantly enhanced the partitioning of both diclofenac and ibuprofen into human skin when compared to an aqueous control, pectin and CMC ($p<0.01$). However, although drug partitioning into the skin was highest in the presence of HA, it was not significantly different from that obtained when the other glycosaminoglycans, CS and HP, were employed as the vehicle ($p>0.05$). Results from the Franz cell diffusion studies showed that HA (1% weight/weight) significantly enhanced the amount of drug localizing within the epidermis after 24 h when compared to an aqueous control ($p<0.01$), PT ($p<0.01$), CMC ($p<0.01$) and CS ($p<0.05$). The results suggest that glycosaminoglycans may promote the partitioning of certain drugs into human skin but only HA could be shown to significantly affect the overall intradermal localization after 48 h of application. Thus, the inclusion of hyaluronan as a vehicle excipient offers clear potential in the dermal delivery and localization of drugs.

AB The present invention comprises methods and compns. for topically treating and moisturizing keratinous structures of humans and animals including skin, hair, fingernails, toenails, hooves, and horns. The composition comprises water-dispersible lecithin and compds. selected from the group consisting of elastin, elastin fragments, elastin-glycolic acid, collagen, collagen fragments, yeast exts., skin respiratory factor, glucosamine, glucosamine sulfate, hyaluronic acid, hyaluronate, chondroitin sulfate,

cholic acid, deoxycholic acid, ginseng extract, aloe vera powder, aloe vera oil, RNA and DNA fragments, ascorbyl palmitate, ascorbic acid, retinol palmitate, dehydroxycholesterol, vitamin E, vitamin E lineolate, panthenol Et ether, glycerol ceramides, glycogen, DL-pyroglutamic acid, urea, sodium lactate, lactate, glycerin, sorbitol, oils of borage, evening primrose, black currant, almond and canola, vanishing cream, cholesterol, flavonoids, witch hazel, chamomile, parsley, hibiscus, capric and caprylic triglycerides, amino acids, allantoin, sodium, calcium, potassium, phosphate, chloride, sodium lactate, alpha hydroxy acids, cocoa butter, coconut oil, jojoba oil, safflower oil, wheat germ oil, sesame oil, selachyl alc., shark oil, cerebrosides, proanthocyanidin, farnesol, candelilla, carnauba wax, vitamin E nicotinate, manganese ascorbate, zinc, oleyl alc., polysorbate 80, spermaceti, glycerol monostearate, beeswax, silicone oil, paraffin wax, ozokerite, and PEG 75 lanolin.

AB Cosmetic packs for skin conditioning of the face are prepared in a form of sheet containing chemical modified collagens such as esterified atelocollagens, succinylated atelocollagens, acylated-succinylated atelocollagen, alkali-solubilized collagens, succinylated alkali solubilized collagens, and acylated alkali-solubilized collagens. Hyaluronic acid, chondroitin sulfate, or other mucopolysaccharide may be added. These materials may be laminated with other synthetic polymer films or sheets. As compared to conventional packs, these collagen materials provide moisture to a larger extent and control skin disorders. Thus, 1% solution of succinylated atelocollagen was prepared and used to make 20 μm-thick film by the drum method. The film was soaked with H2O and placed on the skin for 2 h.

AB Chondroitin sulfate (CS) belongs to the group of glycosaminoglycans (GAGs), which are linear polysaccharides, located in the extracellular matrix and on the cell surface. To study the structure and distribution of CS in human skin and skin disorders , we have selected antibodies using phage display technique against CS. Four unique human anti-CS single-chain antibodies were selected: IO3D9, IO3H10, IO3H12, and IO4C2. We determined their amino acid sequence and evaluated their CS reactivity using ELISA and immunohistochemistry. Antibodies were reactive with CS, but not with other GAGs except for IO4C2, which was also reactive with heparin. Antibody IO3D9 showed a strong reactivity with highly sulfated CS (CSE). All antibodies displayed a different staining pattern in rat kidney, indicating the recognition of unique CS epitopes. In normal skin, the papillary dermis but not the reticular dermis was strongly stained. Antibody IO3H12 also stained basal keratinocytes. We applied these antibodies to study CS expression and localization in melanoma and psoriasis. A strong immunoreactivity with the extracellular matrix of melanoma metastases could be observed for all four antibodies, while in atypical nevi a less extensive reactivity with only the papillary dermis was observed. In psoriatic lesions, CS could be observed in the papillary dermis and in the reticular dermis, whereas the specific location in the papillary dermis found in normal skin was completely lost. In conclusion, human phage-display-derived anti-CS antibodies have been selected, characterized, and applied to detect CS alterations in skin conditions. Altered CS composition was detected in melanoma and psoriasis.
